Project Details	
Project Code	IIAR27Br Van der Kamp
Title	Overcoming β-lactamase-mediated antibiotic resistance by combining biomolecular simulation and experiment
Research Theme	Infection, Immunity & Antimicrobial Resistance
Project Type	Other
Summary	Antibiotic resistance threatens human health. β-lactamases cause resistance to β-lactams, the most widely used antibiotics. Class C β-lactamases are not well understood, but variants are emerging that help bacteria evade even 'last resort' treatments. By combining computer simulation (molecular dynamics, reaction simulations) and experimental methods (enzyme assays, crystallography) you will study how, finding links between structure and activity. This will help to regain the upper hand in the 'biochemical warfare' between humans and bacteria.
Description	Rising antibiotic resistance is a major problem for human health. Resistance to β-lactams, the single most important antibiotic class, usually arises through their breakdown by β-lactamases (BLs). Many BL producing bacteria are multi-drug resistant and may cause untreatable infections. Worryingly, new BL variants conferring resistance are detected frequently. Several BLs that are currently distributed world-wide are from the BL classes A (KPC-2), B (NDM-1) and D (OXA-48). However, class C BLs are increasingly detected and involved in causing resistance against 'last resort' treatments such as the ceftazidime-avibactam (AviCaz) antibiotic-inhibitor combination therapy. We have previously shown that for serine BLs from classes A & D, structural and kinetic data combined with multi-scale computer simulations provides detailed insight into the molecular determinants of resistance-conferring activity (e.g. ACS Catal 2020, 2022; ACS Infect Disease 2022, JACS 2023, FEBS Lett 2025, JCIM 2026). Due to the relative lack of experimental data, obtaining such structure-activity relationships of clinically relevant Class C enzymes is still a challenge, although we have recently shown that similar insights are possible (Lima & Van der Kamp, ACS Catal 2025). This multidisciplinary project now aims to combine simulation, structure determination and enzyme kinetics to understand class C BL-driven resistance against key antibiotic treatments in detail. The proposed project will focus on two key aspects: breakdown of cephalosporin beta-lactam antibiotics (BLAs) by class C BLs and the inhibition of class C BLs by diazabicyclooctanone (DBO) β-lactamase inhibitors (BLIs). These two together will determine the resistance that BLs will confer against 'last resort' BLA/BLI combination therapies. Throughout, computational and experimental work will be closely integrated. Computational analysis of crucial interactions, catalytic mechanisms, reaction intermediates and conformational behaviour (Van der Kamp) will test hypotheses and help analyse enzyme kinetics (Tooke, Spencer). X-ray crystallography (Tooke, Spencer) will provide the necessary structural data to verify initial hypotheses and allow additional computational modelling. The project will focus on a set of Class C BLs from both chromosomal and plasmid origin where changes in different regions have been shown to increase resistance. Initially, outstanding questions on the detailed mechanism will be addressed. Then, multiscale computational 'assays' will be designed to efficiently predict activity

	differences (by comparison to existing and new experimental data). This is likely challenging, as exact structures of the variants of interest in complex with the BLAs and BLIs are typically not available. Alongside using recent advances in AI structure prediction (e.g. AlphaFold3), structures of selected BL-BLA/BLI complexes will be determined experimentally (as these are often not predicted with sufficient accuracy by AI for new variants). Based on the information gained, we aim to predict new putative resistance-conferring BL variants from computational screening of mutations at key positions, and validate these predictions with experimental determination of beta-lactam hydrolysis and inhibition using steady-state, and state-of-the-art stopped- and quenched-flow kinetic methods, along with parallel investigation of antibiotic susceptibility in bacterial killing assays. The project will provide training in cutting-edge techniques in complementary disciplines (computational chemistry, molecular biology/biochemistry) using state-of-the-art facilities in the context of a highly collaborative AMR research environment. It will benefit from Bristol and GW4's excellent resources for high-performance computing and access to X-ray facilities. Mechanistic insights of Class C BL conferred antibiotic resistance can inform both the use of existing antibiotics and the possible development of new beta-lactam antibiotics to evade BL-mediated resistance. To accelerate knowledge transfer, findings will be discussed with our network of local, national and international collaborators prior to publication. We will also exploit the broad interest in antimicrobial resistance through public engagement activities.
Can be completed part time?	Yes
Supervisory Team	
Lead Supervisor	
Name	Professor Marc Van der Kamp
Affiliation	Bristol
College/Faculty	Faculty of Health and Life Sciences
Department/School	School of Biochemistry and Biomedical Sciences
Email Address	marc.vanderkamp@bristol.ac.uk
Co-Supervisor 1	
Name	Dr Catherine Tooke
Affiliation	Bath
College/Faculty	Faculty of Science
Department/School	Department of Life Sciences
Co-Supervisor 2	
Name	Professor Jim Spencer
Affiliation	Bristol
College/Faculty	Faculty of Health and Life Sciences
Department/School	School of Biochemistry and Biomedical Sciences
Co-Supervisor 3
